Checking the summary against the code

CodeRabbit Change Stack | Formbricks #8650 | Parth Pawar

The brief was to make Change Stack easier to use without losing its capability. I prioritized finding the right lines, keeping a way back and grouping the controls. I explored four directions, chose M because it keeps layers, and worked with this PR's existing content.

What I noticed	What I changed
Six summary points share L49–130. I still have to find the lines behind each point.	I gave each point a smaller target. The full wording and surrounding code stay available so I can check beyond the highlight.
The access check continues in another file.	Inspect guard opens both checks. Return brings me back to the caller's selection and reading position. I mapped this route manually.
File and display actions sit across several controls.	I put file actions beside the filename and display settings above the code. Less-used tools sit in named menus, which adds a click.

Why I kept one code pane

Showing the caller and guard together squeezed both at laptop width, so I chose Return. Both comparison screens use Unified. The original fits more code; M gives files and summary links more room. Focus gives that space back.

What stays available

PR details, icons, layer numbers and file positions remain visible. Visiting a file leaves progress alone; Mark viewed and Undo change it. Secondary tools have named destinations. The presentation's capability map distinguishes working interactions from previews.

What I would test

I'd ask developers to explain the access check on both screens, then find something the summary might miss. I'd watch for wrong turns and missed branches. If smaller highlights lead people to overlook code, I'd change them.

This prototype covers seven of 52 diffs at commit 23cdac2. Links are manually mapped. The PR is merged; Submit is disabled. Semantic diffs and modified-file review are outside this sample. I have not tested it with developers.
